Primary colon cancer: ESMO Clinical Recommendations for diagnosis, adjuvant treatment and follow-up

E. Van Cutsem¹ & J. Oliveira²
On behalf of the ESMO Guidelines Working Group*

¹Digestive Oncology Unit, University Hospital Gasthuisberg, Leuven, Belgium; ²Service of Medical Oncology, Portuguese Institute of Oncology, Lisbon, Portugal

incidence
In 2006 there were 412,900 new cases of colorectal cancer in Europe. This is 12.9% of all cancer cases. Colorectal cancer was responsible for 217,400 deaths in Europe in 2006. This represents 12.2% of all cancer deaths.

diagnosis
The diagnosis of a colonic adenocarcinoma requires a histopathologic confirmation taken via colonoscopy/sigmoidoscopy. Risk factors including familial and/or hereditary predisposition, location, and histological evaluation of colonic tumors should be documented.

staging and risk assessment
Staging provides essential prognostic information relevant for choosing adequate therapy and should also identify patients with resectable distant metastases.

Preoperative staging consists of clinical examination, blood counts, liver and renal function tests, carcino-embryonic antigen (CEA), chest X-ray or preferably chest CT-scan, CT scan of the abdomen including the pelvis and a colonoscopy of the entire large bowel, i.e. with postoperative repeat colonoscopy if proximal parts of the colon were not accessible preoperatively.

Pathologic staging should be done according to the 2002-TNM system with optional listing of the modified Dukes stage, as described in Table 1.

Risk factors for colorectal cancer are: family history, familial adenomatous polyposis (FAP) and attenuated FAP (AFAP) syndromes, hereditary non-polyposis colorectal cancer (HNPPC) syndrome, past history of colorectal cancer or adenoma, chronic ulcerative colitis and Crohn’s disease.

prognosis
Survival rates have been published from the SEER US national cancer registry from January 1, 1991 through December 31, 2000 based on data from 199,363 patients according to the new AJCC sixth edition staging. Overall 5-year colon cancer-specific survival for this entire cohort was 65.2%. Five-year colon cancer-specific survival by stage was 93.2% for stage I, 84.7% for stage IIa, 72.2% for stage IIb, 83.4% for stage IIIa, 64.1% for stage IIIb, 44.3% for stage IIIc and 8.1% for stage IV cancer. Another large analysis based on the US National Cancer database showed in 50,042 patients from 1987 till 1993 a 5-year survival rate of 59.8% for stage IIIa, 42.0% for stage IIIb and 27.3% for stage IIIc colon cancer.

treatment
Surgery is the mainstay in the management of patients with colon cancer. The primary goal is a wide resection of the primary tumor with all locoregional lymph nodes. Optimal surgery by experienced colorectal surgeons should be performed. An adequate number of lymph nodes should be recovered (at least 12) and resection margins have to be free. Laparoscopic resection gives similar oncologic outcome compared to laparotomy and has less postoperative morbidity in experienced surgical hands.

Adjuvant chemotherapy is recommended for stages T1-4, N1-2, M0 (i.e. stage III, modified Dukes C1-3). In stage III colon cancer adjuvant chemotherapy significantly improves the disease-free survival (DFS) and overall survival [I, A]; the absolute survival benefit is approximately 15%. Adjuvant chemotherapy can be considered in selected node-negative patients, especially if high risk factors for recurrence are found. The UK Quasar study that randomized patients postoperatively between no treatment and adjuvant 5-fluorouracil (5-FU) based therapy (mainly with leucovorin) has shown a small but statistically significant improvement in 5-year survival in unselected patients (mainly stage II).

Subgroup analyses of the stage II patients in the randomized studies comparing 5-FU/LV and 5-FU/LV/oxaliplatin (FOLFOX) suggests also an improved DFS in patients with high risk stage II colon cancer. Amongst the known high risk factors in stage II colon cancer are: T4, poorly differentiated adenocarcinoma/undifferentiated...
There is no strong proof that regular follow-up after successful follow-up is now considered as an appropriate and 5-year survival in the adjuvant treatment of colon cancer.

Clinical recommendations on advanced colorectal cancer.

Metastatic disease is a specific situation addressed in ESMO clinical recommendations.

The recommended duration of adjuvant chemotherapy is 6 months for colon cancer in patients fit for combination chemotherapy. 

Options for adjuvant treatment include infusional 5-fluorouracil (5-FU)/LV-regimens without or with oxaliplatin and capcitabine with and without oxaliplatin. Capcitabine has been shown to be at least as effective and less toxic as bolus 5-FU/LV. 

The combination of 5-FU/LV plus oxaliplatin significantly improves the DFS in high risk stage II and III colon cancer and improves also the overall survival in stage III colon cancer compared to 5-FU/LV. 

The combination of a fluoropyrimidine plus oxaliplatin has therefore become the standard adjuvant treatment for stage III colon cancer in patients fit for combination chemotherapy. 

The recommended duration of adjuvant chemotherapy is 6 months, starting as soon as the patent is recovered from the surgery and optimally within 6 weeks after the surgical intervention.

The adjuvant treatment after complete resection of metastatic disease is a specific situation addressed in ESMO clinical recommendations on advanced colorectal cancer.

A good correlation has been shown between the 3-year DFS and 5-year survival in the adjuvant treatment of colon cancer. Three-year DFS is therefore now considered as an appropriate endpoint in the adjuvant treatment of colon cancer. 

Follow-up

There is no strong proof that regular follow-up after successful treatment improves the outcome of patients with colorectal cancer.

However, it may be clinically beneficial to identify recurrence of colon cancer in a stage at which its diagnosis will have therapeutic implications (i.e. surgery for metastatic disease or for local recurrence).

In the absence of an evidence-based standard, a provisional recommendation to identify patients in need of salvage surgery and to prevent second colorectal cancers is the following:

- History and physical examination and CEA determination (if initially elevated) every 3–6 months for 3 years and every 6–12 months year 4 and 5 after surgery. Colonoscopy at year 1 and thereafter every 3 years to look for metachronous adenomas and cancers.
- CT scan of the chest and abdomen every 6 months for 3 years can be considered in patients who are higher risk for recurrence.
- Other laboratory and radiological examinations are of unproven benefit and shall be restricted to patients with suspicious symptoms.

Note

Levels of evidence [I–V] and grades of recommendation [A–D] as used by the American Society of Clinical Oncology are given in square brackets. Statements without grading were considered justified standard clinical practice by the experts and the ESMO faculty.

Literature

Primary colon cancer: ESMO Clinical Practice Guidelines for diagnosis, adjuvant treatment and follow-up R. Labianca, B. Nordlinger, G. D. Beretta, A. Brouquet & A. Cervantes On behalf of the ESMO Guidelines Working Group. About 70% of patients with colon cancer are >65 years of age and the disease is rare under the age of 45 (2 per 100 000/year). Survival in Europe the relative survival for adults diagnosed with colon cancer during 1995-99 was 72% at 1 year and 54% at 5 years. Suggested recommendations are as follows. Intensive follow-up must be performed in
